Among these, the most remarkable case is No. 1923, page 140, of the VII<sup>th</sup> Vol., where an additional correction of 2' 55" has been made. Here an error of 1' 5" had been assumed, owing to various mistakes, instead of one of 4' 0".

## Stars having Peculiar Spectra.

(Communicated by Edward C. Pickering, Director of Harvard College Observatory.)

An examination of photographs of stellar spectra, taken at the Peruvian Station of the Harvard College Observatory, under the direction of Professor S. J. Bailey, and forming part of the work of the Henry Draper Memorial, has added five faint objects to the list of stars having spectra of the fifth type. This increases the known number of these objects to 60. Two new gaseous nebulae have also been found in this examination. These two gaseous nebulae, together with that announced in the Astr.

Nachr. Vol. 128, p. 12, make three of these interesting objects which have been discovered at this Observatory by means of their photographic spectra. The approximate right ascensions and declinations for 1900, of these objects are given in the first and second columns of the following table, and their Galactic longitudes and latitudes in the third and fourth columns. The last column gives a brief description of the object.

$\alpha$ 1900	$\delta$ 1900	Gal. Long.	Gal. Lat.	Description
13 <sup>h</sup> 46 <sup>m</sup> .5	-66° 1'	276° 42'	-4° 52'	Type V
15 10.0	-45 17	295 43	+9 10	Type V <i>Gas. neb. Sec A. 2, 137, 14</i>
17 11.8	-34 18	319 58	+0 32	Type V
17 18.2	-43 24	313 10	-5 39	Type V
17 38.2	-46 3	312 48	-10 4	Type V
18 39.3	-33 27	329 41	-14 52	Gaseous Nebula
19 10.5	-39 47	325 50	-22 29	Gaseous Nebula

*Harvard 2nd Neb. 18*

The second star in the above list was found by Mr. Luis Duncker in Peru.

NGC. 6768 precedes the last object in the list  $0^m 9$  and is  $35'$  south, but it does not appear in the photograph on which the new gaseous nebula was discovered.

In addition to the objects mentioned above, two stars whose approximate positions for 1900 are in RA.  $13^h 26^m 4$ , Decl.  $-53^\circ 19'$ , and RA.  $14^h 52^m 2$ , Decl.  $-53^\circ 0'$  have been found to possess spectra of the fourth type. The first of these is identical with Cord. ZC.  $13^h 1490$  mag. 9.6.

Each of the above positions, except that of Cord. ZC.  $13^h 1490$ , was obtained from three or more adjacent catalogue stars, and the positions derived from the different stars differs on the average by less than one minute of arc. These positions, like those I have previously published in the Astr. Nachr., in announcing new variable stars, and other objects having peculiar spectra, are, as has been

stated in each case, only approximate. The earlier positions, especially those of the six stars given in the Astr. Nachr. Vol. 130, p. 125, are less accurate than those I have given subsequently, since they were found by superposing the photographic plates on manuscript charts and reading off the approximate positions. Two of these six stars are within four degrees of the south pole and the error in right ascension, expressed in time, as compared with equatorial stars, is therefore magnified about seventeen times. To afford an additional indication that the right ascensions of these stars were less accurate the tenths of a minute were omitted. More accurate places were afterwards published in Astronomy and Astro-Physics, but as both series of positions were stated to be approximate, it has not been thought necessary to call attention to their differences until the exact positions could be given.

### Éléments elliptiques de la comète 1894 . . . (Denning mars 26).

Ayant reçu de l'obligeance de M. Bigourdan une nouvelle observation du 25 avril, j'ai d'abord calculé l'orbite parabolique donnée ci-après à l'aide de trois lieux correspondant aux dates: 27 mars (15 obs.), 10 avril (1 obs.) et 25 avril (1 obs.). Les éléments paraboliques représentant mal le lieu intermédiaire, j'ai ensuite déduit une orbite elliptique qui est encore assez incertaine et qui assigne à la comète une période de 6.745 années.

#### I. Orbite parabolique.

$$T = 1894 \text{ févr. } 14.27241 \text{ t. m. de Paris.}$$

$$\begin{aligned} \pi &= 133^\circ 30' 19.^s 6 \\ \Omega &= 75^\circ 9' 6.4 \\ i &= 6^\circ 31' 47.7 \end{aligned} \quad | \quad 1894.0$$

$$\log q = 0.088150$$

$$\Delta\lambda_2 = -23.^s 1, \quad \Delta\beta_2 = -37.^s 5.$$

#### II. Orbite elliptique.

$$T = 1894 \text{ févr. } 9.08813 \text{ t. m. de Paris.}$$

$$\begin{aligned} \pi &= 130^\circ 22' 50.^s 2 \\ \Omega &= 85^\circ 2' 50.0 \\ i &= 5^\circ 27' 36.2 \end{aligned} \quad | \quad 1894.0$$

$$\varphi = 42^\circ 50' 47.6$$

$$\mu = 526.^s 079$$

$$\log a = 0.552637$$

$$\Delta\lambda_2 = +5.^s 8, \quad \Delta\beta_2 = +2.^s 4.$$
